# ***Introduction – objectives of the presentation***

The presentation discusses a demonstrator built for the European Commission's DG FISMA and show how smart contracts can implement 'digital doppelgängers' of OTC derivatives contracts that are traded to help achieve the policy objective of 'report once'.

## **EC DG FISMA**

The Directorate-General for *Financial Stability, Financial Services and Capital Markets Union* is the Commission department responsible for EU policy on banking and finance.

## **OTC derivatives**

Derivatives are financial instruments whose value depends on ('derives from') the values of other, more basic, underlying variables e.g. a stock of a company, or an index such as S&P. Over-the-counter (OTC) derivatives are customized, bilateral agreements that transfer the risk from one party to the other (such as swaps and forwards).

## **Smart contracts as 'digital doppelgängers'**

Smart contracts are executable pieces of software residing on an electronic distributed ledger. In the presented demonstrator, a private Ethereum ledger was used. The smart contracts are a representation of OTC derivatives

---

# ***Overview of the project***

## **Objectives of the project**

Explore possibilities to address the problems of cost of regulatory burdens for banks and financial institutions and inadequate monitoring of risk attached to financial contracts.

Study investigated the feasibility of Distributed Ledger Technologies (DLTs) as the new way of financial institutions to meet their reporting obligations as laid down in EU financial sector legislation.

## **Novelties**

- resulting demonstrator uses smart contracts to meet the policy objective "report once" in financial reporting (EMIR, MIFIR, COREP) in the EU
- Use of ACTUS semantics

---

## ***Overview of the regulations***

**EMIR** (European Market Infrastructure Regulation) provides that some classes of OTC derivative transactions have to be cleared through Central Counterparties (CCPs), and that risk mitigation techniques have to be applied for other OTC transactions

**MiFIR** extends the clearing obligation by CCPs to regulated markets for exchange-traded derivatives

**COREP**, issued by EBA, specifies Guidelines for Common Reporting:

- for Capital Requirements Directive (CRD) reporting
- covers credit risk, market risk, operational risk, own funds and capital adequacy ratio
- when trading each counterparty conducts its own reporting to its own supervisor

---

# ***Overview of the demonstrator***

- The demonstrator shows
  - How digital representations of *Over The Counter (OTC)* derivatives such as bonds or swaps can be implemented as smart contracts on a blockchain. The life-cycle of the derivatives during trading follows the real assets' life-cycle in semi real-time.
  - How blockchain-based reports can assemble and calculate the information required for compliance reporting (COREP, EMIR, MIFIR) towards supervisory bodies
- Today, this reporting information is typically dispersed and difficult to obtain and correctly aggregate. However, in the demonstrator, as all the is present on-chain, these reports contain all required information ('report once')
- The demonstrator is a vehicle to demonstrate Distributed Ledger Technology (DLT) concepts, it is not an implementation of a target solution

# Distributed ledgers in one minute

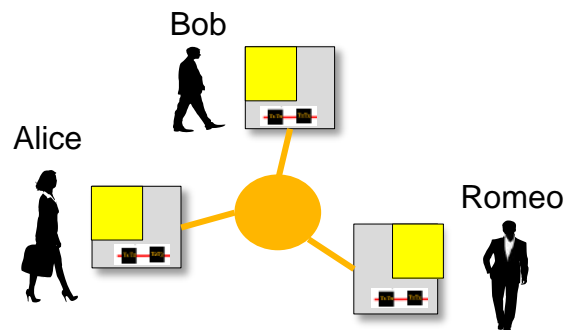

## Vocabulary

- Users (Alice, Bob, Romeo, ...) 
- Applications (cryptocurrency wallet, digital doppelgänger, ...) 
- Nodes (alternatively called 'blockchain nodes') 
- Blockchain (concatenation of blocks) 
- 'Consensus' (all nodes agree on which blocks are part of the blockchain)

## Single node:

## Set of nodes:

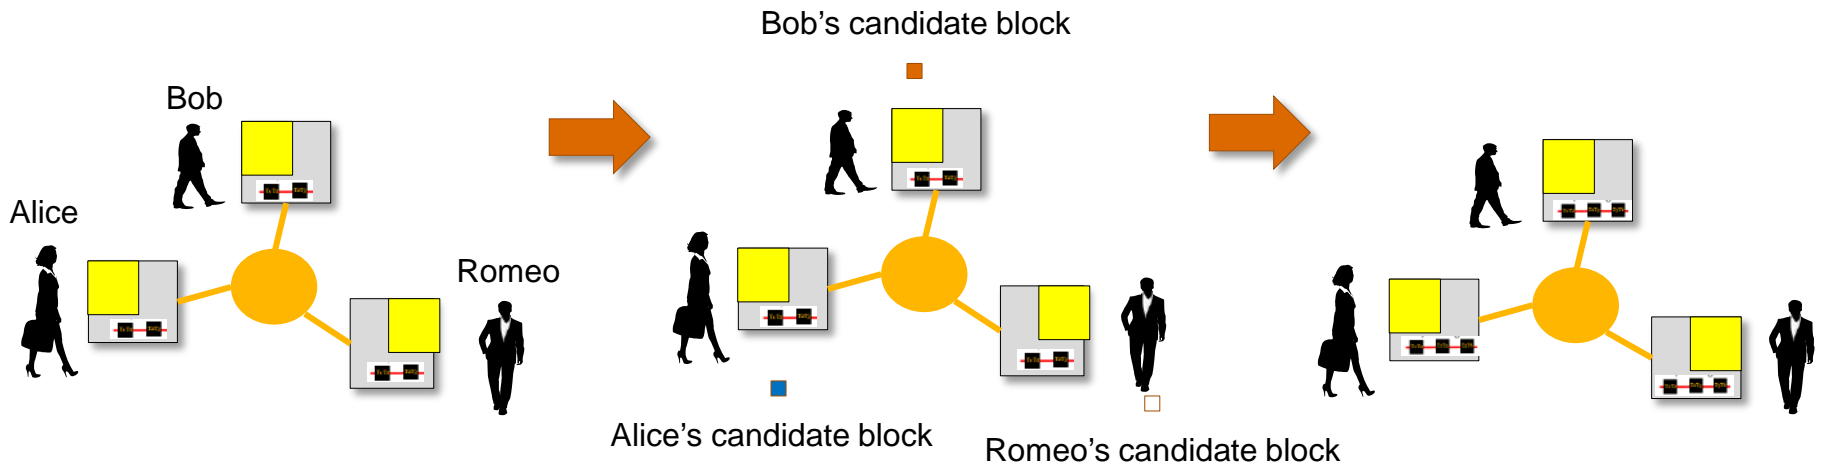

All nodes have an identical copy of the blockchain  
What is stored in the blockchain is considered immutable

# Distributed ledgers in one minute

Users perform transactions through the application  
Every node broadcasts its transaction outputs  
Every node can create its candidate block

Blockchain is extended everywhere  
by selected candidate block

## Which candidate block gets selected?

In most blockchain implementations, nodes try to solve a cryptopuzzle (mathematically hard problem based on hashing), and the first node that solves the puzzle has its candidate block accepted by the other nodes

Once new block is part of the chain, it is considered as immutable, and the transactions as committed on a ledger

## Consensus is important

Ensures that the next block in a blockchain is the one and only version of the truth,  
Keeps powerful adversaries from derailing the system and successfully forking the chain  
There are many different ways to obtain consensus

---

# ***The smart contract demonstrator***

## **Functionality of the demonstrator**

Contracting parties (Alice, Bob, Eve)

- trade OTC derivatives through their usual channels
- have a user interface at their disposal to create *digital doppelgängers* on the distributed ledger

These *digital doppelgängers* are replicated to all nodes on the ledger according to the consensus protocol

Every node, including the regulator (Romeo) has access to the same information in semi-real time

Every node can produce the compliance reports

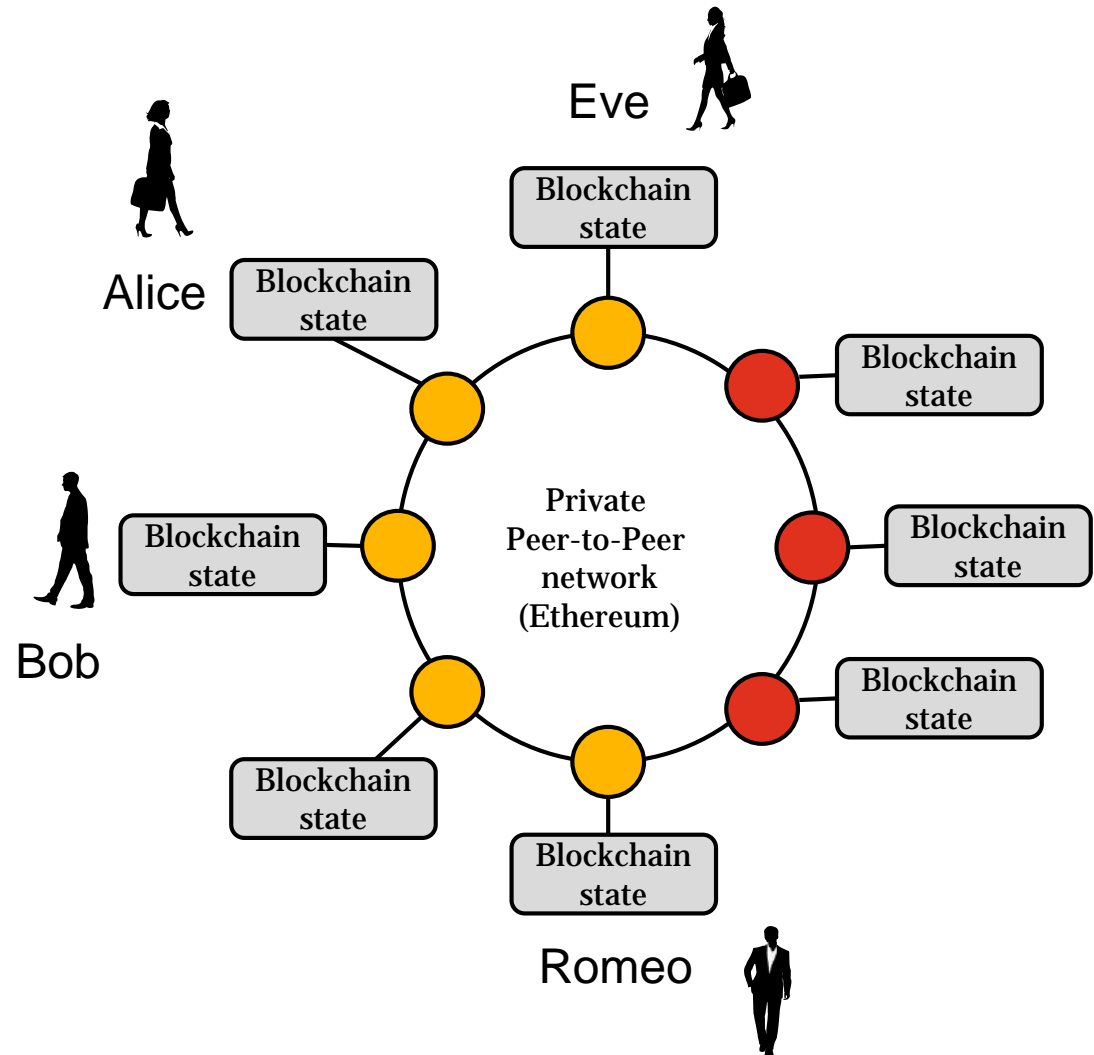

# Set-up of the demonstrator (conceptual)

## Two types of nodes

-  Raspberry PI (Ethereum node, not mining)
-  Laptop (Ethereum node, mining)

Raspberry PI

---

## ***Set-up of the demonstrator***

### **Specific aspects:**

Client requested to demonstrate cheap 25 € computers (Raspberry Pi's) could also run a node

However, these:

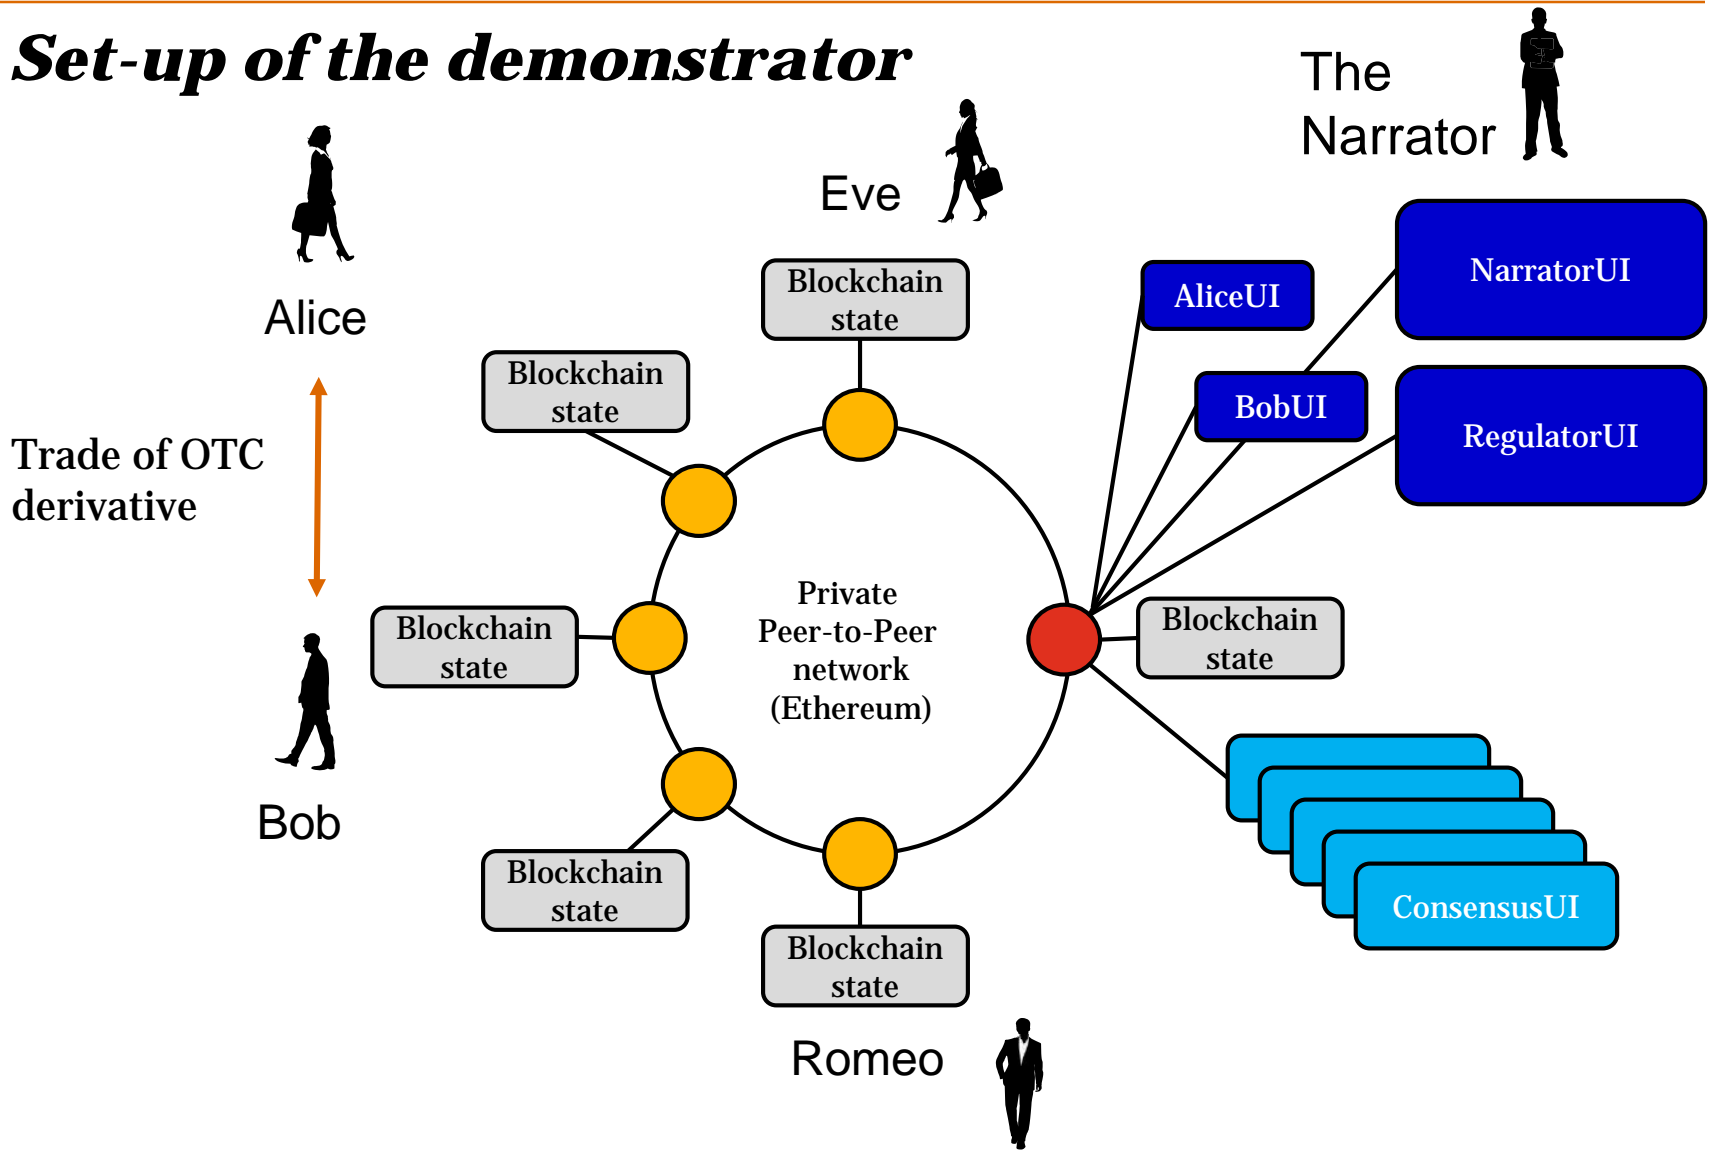

- Do not have a screen to run a user interface
- Do not have sufficient computing power to mine

As a consequence:

Standard off-the-shelve laptops were added to run the UI and do the mining

Furthermore, a dedicated user interface was developed to visualise the consensus

# Set-up of the demonstrator

---

## ***OTC Derivatives as smart contracts***

A 'Smart Contract' is essentially a piece of software. It forms a contract capable of automatically enforcing itself, without a third party between individual participants. It is created and executed on the distributed ledger.

It contains the **contract logic**, the rules of what should happen at a certain point:

And it contains the **contract state**, in our case meaning interest rate, duration of the contract, nominal value, etc.

For this demonstrator we implemented two contracts:

- Bond (based on Actus PAM contract)
- Interest Rate Swap or IRS (based on Actus 'Plain Vanilla' PVSWAP contract)

# Bond

<b>What</b>	<b>Implemented as</b>
A bond is a <b>debt investment</b>	A Smart Contract type that can be created on the blockchain, each contract has its ContractID (CID)
in which an investor loans money to the issuer which borrows the funds,	RecordCreator (LEIRC) and Counterparty (LEICP), specifying a currency (CUR) and NotionalPrincipal (NT)
for a defined <b>period of time</b> ,	MaturityDate (MD)
at <b>variable or fixed</b> interest rate,	e.g. National Nominal Interest Rate (IPNR)
paid at <b>specific dates</b> ,	Cycle anchor date of interest payment (IPANX) and Cycle of interest payment (IPCL)
that <b>can be transferred</b> (sold) to another investor.	LEICP can be updated

# Bond (extract only)

```
pragma solidity^0.4.9;
```

```
contract PAM{
```

```
    enum currencies { EUR, USD, GBP, JPY }
```

```
    enum cycles {Y, H, Q, M, W, D}
```

```
    //Actus contract attributes
```

```
    string public CID; // ContractID
```

```
    string public LEIRC; // LegalEntityIDRecordCreator
```

```
    string public LEICP; // LegalEntityIDCounterparty
```

```
    uint128 public CDD; // ContractDealDate = unixtimestamp
```

```
    uint128 public IED; // InitialExchangeDate = unixtimestamp
```

```
    uint128 public MD; // MaturityDate = unixtimestamp
```

```
    uint128[2] NT; // NotionalPrincipal
```

```
    currencies public CUR; // Currency
```

```
    uint128[2] IPNR; // National Nominal Interest Rate
```

```
    string public IPDC; // Day Count Convention
```

```
    uint public IPANX; //cycle anchor date of interest payment = unixtime
```

```
    cycles public IPCL; // Cycle of interest payment
```

```
    uint128[2] IPCBA; // InterestCalculationBaseAmount
```

```
    uint256 public SD; // Status Date = unixtimestamp
```

```
//Actus state variables
```

```
    uint128[2] Nvl; // Nominal Value
```

```
    uint128[2] Nrt; // Nominal Rate
```

```
    uint public Led; // Last event Date = unixtimestamp
```

```
//Operational variables
```

```
    bool public initialpaymentdone;
```

```

```

```
.....
```

```
.....
```

```
//Series of setter and getter functions
```

```
// Series of helper functions e.g. for conversions and handing of floats
```

```
function initialise(string _CID, string _LEIRC,
```

```
// idem for _LEICP, _IED, _MD, _NT, etc
```

```
{periodCounter = 0;
```

```
    active = true;
```

```
    CID = _CID;
```

```
    LEIRC = _LEIRC;
```

```
    LEICP = _LEICP;
```

```
    IED = _IED; // initial payment day
```

```
    MD = _MD; // end date of the contract
```

```
    NT = _NT;
```

```
    CUR = currencies(_CUR);
```

```
    IPNR = _IPNR;
```

```
    IPDC = "30/360";
```

```
    IPANX = _IPANX;
```

```
    IPCL = cycles(_IPCL);
```

```
    IPCBA = _IPCBA;
```

```
    SD = now;
```

```
    Nvl = _NT;
```

```
    Nrt = _Nrt;
```

```
    Led = SD;
```

```
}
```

```
// advance the period with 1
```

```
function nextPeriod() constant returns (bool){
```

```
    Led = SD;
```

```
    SD = now;
```

```
    periodCounter += 1;
```

```
}
```

```
function setDefault(){
```

```
    defaulted = true;
```

```
}
```

```
}
```

# Swap

<b>What</b>	<b>Implemented as</b>
A swap is a transaction between two parties	A Smart Contract type that can be created on the blockchain, each contract has its ContractID (CID) Parties are the RecordCreator (LEIRC) and Counterparty (LEICP),
These two parties agree to exchange cash flows in the future	Agreeing on the value for the swap, coded in nominalValue  Agreeing on fixed parameters, coded in: fixedRate (interest rate) and fixedPayout (value),  Agreeing on variable parameters, coded in variableRate (interest rate) and variablePayout (value)
They agree about the specific dates when the cash flows are to be paid	There is a start date SD, and a maturity date MD  There is a constant defined that specifies the periods per year, PPY = 4, and a counter maintaining the contract's period
that <b>can be transferred</b> (sold) to another investor.	LEICP can be updated

# *Swap (extract only)*

```
pragma solidity^0.4.9;
contract PAM{
    enum currencies { EUR, USD, GBP, JPY }
    enum cycles {Y, H, Q, M, W, D}

    //Actus contract attributes
    //Actus state variables
    //Operational variables

    // Getter, setter and helper functions ....

    function nextPeriod() returns (int128){
        periodCounter += 1;

        fixedPayout = [(((nominalValue[0])*fixedRate)/100) / 4,nominalValue[1]];
        variablePayout = [(((nominalValue[0])*variableRate)/100)/4,nominalValue[1]];
        payoutValue = [(fixedPayout[0]/fixedPayout[1]) - (variablePayout[0] / variablePayout[1]),1];
    }

    .....
}
```

---

# ***Set-up of the demonstrator***

Actors:

- **Alice, Bob and Eve** are contracting parties, using their respective *AliceUI* and *BobUI* (UI: UserInterface)
- **Romeo**, party with the reporting application, using the *RegulatorUI*
- **The Narrator**, tells the stories, uses the *NarratorUI*
  - Story 1: Bond, where Alice lends money to Bob and later merges with Eve to form AliceEve
  - Story 2: Interest Rate Swap, where Bob creates contract towards AliceEve and creates a new 'PlainVanillaSwap' (PVSWAP) contract with her
  - Story 3: AliceEve defaults on the PVSWAP contract
  - Showing the contents of the DLT, generating reports (EMIR, MIFIR, COREP) and demonstrating consensus takes place during the stories

---

## ***Demonstrator Story 1: Bond***

- In this story, Alice and Bob conclude a bond contract.
- On the blockchain a digital doppelgänger of this contract is created, and through consensus this appears in each node
- The Narrator simulates that time is advanced to the next quarter
- Romeo generates a regulatory report, a COREP report
  - All data available on-chain according ACTUS semantics
  - Hence all calculations can be performed in real-time
  - And report is available immediately

# 1 Contract creation

**Contract ID:**

**Owner:**

**Counterparty:**

**Initial exchange date:**

**Maturity date:**

**Notional principal:**

**National nominal interest rate (%):**

**Interest cycles start date:**

**Interest cycles:**

## 2 Consensus visualisation (consensus not yet achieved)

The screenshot displays four browser windows, each showing a consensus visualization with three panels: Root Hash, Chain Height, and Nonce accepted. The visualizations are as follows:

- Top-left window (IP: 10.0.0.10):** Root Hash: Y; Chain Height: ..18; Nonce accepted: Z.
- Top-right window (IP: 10.0.0.11):** Root Hash: N; Chain Height: ..17; Nonce accepted: F.
- Middle-left window (IP: 10.0.0.12):** Root Hash: N; Chain Height: ..17; Nonce accepted: F.
- Middle-right window (IP: 10.0.0.13):** Root Hash: Y; Chain Height: ..18; Nonce accepted: Z.
- Bottom-left window (IP: 10.0.0.14):** Root Hash: W; Chain Height: ..16; Nonce accepted: F.

A central text box overlaid on the middle-right window reads "2 Contract visualisation".

### 3 Consensus visualisation (consensus achieved)

The image shows a video player interface with five browser windows displaying consensus data. Each window shows three panels: Root Hash, Chain Height, and Nonce accepted. The data is consistent across all windows, indicating consensus has been achieved.

Root Hash	Chain Height	Nonce accepted
<b>C</b> 0x5ce586b5e244dce0b34ab61fb2bacd 7400329bceb234a1f168756810f8dea2	<b>..10</b> 5110 #5110	<b>H</b> dbc054b79035db6 174d7806056da4036d452efbba778824

## 4 Contract visualisation

The screenshot shows a web browser window with the title 'FISMA-v2' and the address bar displaying 'localhost:3100'. The application's navigation bar includes 'Narrator UI', 'Merge counterparties', 'Contracts', and 'Select node -'. The main content area displays 'Current interest rate: 2%' and a section titled 'Contracts:'. Below this is a table with the following data:

Contract Type	ID	Owner	Counterparty	Initial exchange date	Maturity date	Nominal value	
PAM	Contract 1	Alice	Bob	22-9-2017	22-9-2020	34500	<a href="#">View details</a> <a href="#">Default next quarter</a>

Below the table, it shows 'Current quarter: Q2 2017' with a 'Next quarter' button.

## 5 Report generation

FISMA-v2 corep\_report (1).xlsx - LibreOffice Calc

File Edit View Insert Format Sheet Data Tools Window Help

1. Credit Risk: Credit and counterparty credit risks and free deliveries: standardised approach to capital requirements

Number	Field name	Details to be reported	Value
1	Exposure class	Indicates the specific class in which the exposure will be classified according to Article 112 of CRR.	Exposure to institution
2	SME	Indicates if the exposure value is an exposure towards a Small or Medium-sized Enterprise.	No
3	SME subject to SME supporting factor	If the exposure value represents an exposure towards a Small or Medium -sized Enterprise, this field indicates if the SME is subject o the SME-supporting factor according to the requirements of Article 501 of the CRR.	No
4	Exposure type	Indicates the exposure type.	Derivatives and long settlement transactions
5	On-balance sheet or off-balance sheet exposure	Indicates if the exposure appears on the company's balance sheet or not.	On-balance sheet
6	Centrally cleared?	Indicates if the derivative is centrally cleared through a Qualifying Central Counterparty.	Yes
7	Securities Financing Transactions	Indicates if the transaction is a Securities Financing Transaction (SFT), as defined in paragraph 17 of the Basel Committee document 'The Application of Basel II to Trading Activities and the Treatment of Double Default Effects'; includes: (i) Repurchase and reverse repurchase agreements defined in Article 4 (82) of CRR as well as securities or commodities lending and borrowing transactions; (ii) margin lending transactions as defined in Article 272 (3) of CRR.	No
8	Contractually Cross Product Netting?	Indicates that due to the existence of a contractual cross product netting (as defined in Article 272 (11) of CRR cannot be assigned to either Derivatives & Long Settlement Transactions or Securities Financing Transactions) shall be included here.	No
9	nth to default credit derivative?	Indicates if the exposure is related to a derivative where the nth default among the exposures shall trigger payment	No
10	Original exposure pre conversion factors	The exposure value without taking into account value adjustments and provisions, conversion factors and the effect of credit risk mitigation techniques.	1.189,72
11	Value adjustments and provisions associated with the original exposure	Value adjustments and provisions for credit losses made in accordance with the accounting framework to which the reporting entity is subject to.	0,00
12	Exposure net of value adjustments	Net exposure which is the difference between (8) and (9).	1.189,72

Sheet 1 of 2 PageStyle\_Credit risk Sum=0 100%

---

## ***Demonstrator constraints***

In the current demonstrator implementation:

- In the current set-up of the demonstrator, for simplification reasons, contracting information is reflected in the DLT, and all participants have access to it (may not be desirable for a production system)
- The contracting which takes place between parties is supposed to take place outside the blockchain universe (via phone or via another application)
- Only these contracts are then created on the blockchain
- The identities of the parties is not cryptographically confirmed (production system would do this e.g. with electronic authentication)
- The identity and state of the parties (e.g. legal entity definition, identity attributes, defaulted or not) is not maintained on the blockchain
- The authenticity of the contract itself is not cryptographically confirmed (production system would do this e.g. with electronic signatures)
- Valuation is done within the reporting application, taking into account the data on the blockchain as well as external data (currently hardcoded)

---
